ABSTRACT OF THE RESULTS OF 1942 FOREST INSECT SURVEY  
STANISLAUS NATIONAL FOREST, CALIFORNIA

A. The 1941 Infestation (completed records).

1. Total pine timber killed on reporting areas. (Tables 2 and 3)

a. Number of trees, PP-SP-JP.	2,961
b. Volume, PP-SP-JP.	2,399,000 board feet
c. Average volume per acre, PP-SP	12 board feet
JP	4 board feet

2. Present classification - low endemic.

3. Primary insects - Western pine beetle in ponderosa pine  
Mountain pine beetle in sugar pine  
Jeffrey pine beetle in Jeffrey pine.

4. Trend - substantial decrease over 1940.

5. Control work completed - Direct control work by the peeling-burning method was carried out in June, 1942, on the Pinecrest Unit. This project was recommended by the Bureau of Entomology following the survey of October, 1941, when it was found that an aggressive infestation of the mountain pine beetle was threatening the mature to old sugar pine in the virgin stands of the commercial-recreational area. The project embraced an area of 5,760 acres. A total of 46 large-sized sugar pine trees infested with broods of the mountain pine beetle were treated. The loss reduction during the first year after control amounted to 93 percent.

B. The 1942 Infestation (partial records).

1. Primary insects - Western pine beetle in ponderosa pine  
Mountain pine beetle in sugar pine  
Jeffrey pine beetle in Jeffrey pine.

2. Probable trend - reduction over 1941.

3. Control recommended - none.

FOREST INSECT SURVEY - SEASON OF 1942  
STANISLAUS NATIONAL FOREST, CALIFORNIA

INTRODUCTION

The annual forest insect survey of the Stanislaus National Forest was made on October 16-18, 1942, by J. E. Patterson and G. R. Struble of the Berkeley Station of the Bureau of Entomology and Plant Quarantine. This survey, in line with surveys of previous years, was made to determine the extent and character of insect-caused losses to ponderosa pine, sugar pine and Jeffrey pine.

At the outset, it was found that the type of survey formerly followed on this forest was no longer possible since many of the virgin stands of timber have been logged, are being logged or are included in current working circles. With the exception of the Mokelumne Plot, all the sample RS survey plots set up on this forest from 1930 to 1934 have either been logged or are immediately adjacent to logged areas which, in either case, render them of little value as infestation indicators. Because of these conditions, the 1942 survey was largely of the reconnaissance type.

Due to the previously described physical changes brought about on this forest, the former method of survey has been made obsolete, and it will be necessary in the future to inaugurate another method making use of a different form of sampling. A form of road-strip sampling for determining and recording insect losses is now being tested and if found adequate will be proposed for future surveys on the Stanislaus National Forest.

The reconnaissance survey of 1942 was amplified by roadside strips in heavily timbered areas which could not be seen from lookout points, or where some sampling of the infestation was desired. These conditions were encountered on the heavily timbered Mokelumne watershed, on the upper Stanislaus River drainage north of Strawberry and in the Buck Meadows district.

Insect losses in general during 1942 were so low that any attempt to estimate the amount of damage in relation to the stand is of little significance. It is estimated that at least 75 percent of the 1942 loss was noted in this survey; the remaining 25 percent will be reported in the 1943 survey record. It was obvious that the infestation had reached a very low point, and in relation to previous infestations should be considered decidedly low endemic.

Accompanying this report are two maps; one of the north Stanislaus, and one of the Stanislaus-Yosemite infestation areas. These have been subdivided into reporting units referred to later in this report. The location of the roadside strips set up in the survey is shown on these maps in red lines.

## RESULTS OF THE SURVEY

### Character of the Infestation:

Western pine beetle activity in virgin ponderosa pine stands during 1942 was confined to occasional trees of intermediate size and decadent crowns. No indications of aggressive attacks were found anywhere in the forest. The infestation was limited to single trees widely separated; grouping of attacks was not observable in any part of the forest. These conditions prevailed in the better type stands in the Mokelumne, Dorrington and Jawbone districts as well as in the fringe type forests in the Groveland-Buck meadows district.

This beetle developed greater activity in the recently logged areas in the Big Creek unit on the south Tuolumne River drainage during the year. Here the reserve stands were generally infested although the infestation cannot be considered epidemic in character. The loss during the year in these reserve stands is estimated to be about 42 trees per section.

Mountain pine beetle activity in virgin pine stands was generally lower than in 1941 on all units. Except for some local activity in sugar pine on the areas north of Cow Creek, the Pinecrest unit which contained the heaviest 1941 infestations on the forest was in 1942 relatively free from attacks. This condition is evidently due to the direct control work carried out on this unit in the spring of 1942 which reduced the beetle population to a low point. The value of this control work is well demonstrated by conditions on the adjacent area north of Cow Creek where losses continued as high as in 1941.

Attacks in Jeffrey pine by the Jeffrey pine beetle along the watershed of the upper middle fork of the Stanislaus River were less than they have been for the past several years. Here again the value of control work is well demonstrated since damaging infestations have not occurred on any part of this watershed following the control work carried out in 1939-1940 in the Clark's Fork and Brightman Flat units.

An indication of the generally low infestations in all species is shown by a tabulation of losses on roadside strips shown in Table 1.

Table 1. Summary of Pine Losses on Sample Roadside Strips.  
Stanislaus National Forest, California.

Unit	Timbered Acreage	Trees Killed			Volume (b.m.) Per Acre		
		PP	SP	JP	PP	SP	JP
Bloods	80 A	0	0		0	0	
Blue Mountain	120 A	0	0		0	0	
Folsom	235 A	1	0		4	0	
Cow Creek	300 A	1	2		24	33	
Clark's Fork	200 A			2			8
Buck Meadows	268 A	1	0		2	0	

The estimated unit pine losses and loss per acre by units from 1940 to 1942 are shown by Tables 2 and 3.

Table 2. Estimated Pine Losses by Entomological Units.  
Stanislaus National Forest - 1940 to 1942, Inclusive.

### Trend of the Infestation:

The pine beetle situation on the Stanislaus Forest showed a marked improvement in 1942. There was a substantial decrease in insect-caused losses as compared to those of the two previous years. This downward trend was general over the entire forest but was more pronounced in the fringe type than in the better sites on the higher elevations. As in 1940 and in 1941, losses on the Mokelumne and Stanislaus units were higher than on the other units of the forest, but these conditions are far from serious and have recently decreased. There was no marked difference in the activity of the three primary insects involved in these infestations, or in the tree species attacked. All showed the same trend toward decreasing infestations.

### Insects Involved:

The western pine beetle, Dendroctonus brevicornis Lec., was the most abundant of the insects found in attacked trees. This species is specific to ponderosa pine. The mountain pine beetle, Dendroctonus monticolae Hopk., was found principally attacking sugar pine, but also sparingly in ponderosa pine. It was the insect primarily involved in the control project carried out on the Pinecrest unit in the spring of 1942, and is the species responsible for the death in 1942 of several large sugar pine trees in the Cow Creek-Niagara Creek area. The Jeffrey pine beetle, Dendroctonus jeffreyi Hopk., was confined to the Jeffrey pine stands and losses in this species were due almost entirely to the activity of this bark beetle.

### RECOMMENDATIONS

No areas on the Stanislaus Forest were found to have infestations sufficiently damaging to warrant direct control measures. On all the units, low endemic conditions prevailed and because of the widely scattered distribution of infested trees and the non-aggressive character of infestations, it is believed that the current low status will prevail through 1943 at least. Certain areas where recent decrease in infestations has not kept pace with general conditions should be watched during 1943 to detect a possible increase in losses. Such conditions are found locally on the Mokelumne and Stanislaus units and in the sugar pine-Jeffrey pine stands between Cow Creek and Niagara Creek.
